## **SAD NO. 223**

### **DRAINAGE MANAGEMENT PLAN**

#### **I. GENERAL**

##### **A. PURPOSE AND AUTHORIZATION**

The preparation of this document was authorized by the Public Works Department, City of Albuquerque, under A/E Agreement No. 4193.01 dated January 11, 1991. Its purpose is to provide the hydrologic basis for the design of the streets and storm drainage systems and to provide a foundation for fair and equitable assessments of storm drainage benefits within Special Assessment District No. 223 (SAD No. 223).

##### **B. DESCRIPTION OF SAD NO. 223**

SAD No. 223 is located within the Seven Bar Sector Plan area (Reference 7) in northwest Albuquerque. It covers 37 parcels (approximately 540 acres) and eight property owners. The district was created to construct major streets, storm drains, water and sewer lines, and landscaping in that portion of Seven Bar Ranch east of Coors Bypass and south of NM 528 (Alameda Blvd.).

##### **C. DESCRIPTION OF DRAINAGE SCHEME**

There are currently no permanent public drainage facilities within SAD No. 223, except for a partially constructed storm drain in Coors Bypass near the Calabacillas Arroyo. Existing drainage patterns can be classified as natural or casual. A significant portion of the area was once Alameda Airport. Very little remains of the natural drainage patterns due to past development-related grading. The resultant drainage patterns described as casual were not specifically designed or planned but just "happened" as roads and runways were constructed.

The Seven Bar Sector Plan Area is divided into two distinct drainage basins: the area west of (above) Black Arroyo/Seven Bar Channel; and the area east of (below) the two channel system. (There are, however, approximately twenty-one acres east of the Black Arroyo which can drain westward into it.)

The area within SAD No. 223 east of the channels has been subdivided further into four sub-basins as shown on Basin Map, Plate A and described below:

1. The area near the **Calabacillas** and **Black Arroyos** which can drain directly to them (50.2 acres). No improvements are proposed impacting this directly connected area.

2. The area within SAD No. 223 which drains to the proposed **Cabezon Channel Outfall System** (approximately 360 acres).
3. The area within SAD No. 223 which drains to the **Corrales Main Canal Outfall System** (approximately 11.4 acres).
4. The area within SAD No. 223 which drains to the **Calabacillas Arroyo Outfall System** (approximately 94.8 acres).

Except for the area draining directly to the Calabacillas (1) and Black Arroyos which can discharge freely, developed discharges in each of the remaining three sub-basins are limited by downstream capacity. Each outfall-constrained sub-basin will require on-site development controls and storm drainage improvements. Each sub-basin system will be discussed in more detail in the following sections.

#### D. COMPUTATIONAL METHODS (Revised 3-92)

##### Background

The drainage criteria and software used for hydrologic and hydraulic analysis varies from system to system in the project. This is a result of revisions made to the drainage criteria during the design period of the project. All hydrologic analysis of the system were originally based on the January 1991, Section 22.2, Volume 2 DPM Drainage Criteria. All original hydrologic modeling was done using the "9-90" version of AMAFCA's AHYMO. During the design phase of the project an update was made to the City of Albuquerque Drainage Criteria and the AMAFCA AHYMO computer model. The revised drainage criteria dated August 1991 and the AHYMO Model dated September 1991 were approved in November of 1991 for use in flood studies in the Albuquerque area by the Federal Emergency Management Agency (FEMA). As a flood plain study was required for an area within the Cabezon Channel Outfall System, the August 1991 criteria and "9-91" Model were utilized in final analysis of this system. The analysis of all other systems in the district was based on the January 1991 criteria and the "9-90" Model.

##### System Modeling

Hydrologic modeling was performed for this project utilizing AMAFCA's AHYMO. AHYMO's Type 2, 24-hour rainfall distributions were used with a  $D_1 = 0.05$  hours. Land treatment types were assigned based upon Seven Bar Sector Plan and uses or more recent zoning designations and the values of imperviousness shown in Section 22.2 of the DPM. Time of concentrations ( $T_c$ ) were derived using the Upland Method as recommended in the DPM. Whenever  $T_c$  was less than 12.0 minutes, 12.0 minutes was assumed. Traditional upland watershed modeling (upstream to downstream) was performed. Hydrographs were computed for each parcel within the district as well as for each street/storm drain sub-reach. Model runs for 100-year, 24-hour, and 10-year,

24-hour storms were performed in order to verify street capacities and satisfy Drainage Ordinance Criteria.

First pass analyses and storm drain routings were performed using normal depth flows (pipe slopes). Modeling results were then provided to the design team. Once preliminary hydraulic design was completed using energy balance methods, pipe diameters and catch basin locations were updated and a verification model run was made. Whenever pressure flow existed, the average friction slope for that reach was substituted for the pipe slope in the model.

Catch basins were first located then modeled based upon their type, capacity, orientation, and resultant capture ability using the "Divide HYD" routine in AHYMO. Divided hydrographs were routed separately in street and pipe routings. In cases where the initial modeling runs indicated all or nearly all of the street flow would be intercepted by a catch basin, the "Divide HYD" routines were removed from the model and all street flow was added to the storm drain.

## **II. CABEZON CHANNEL OUTFALL SYSTEM (Revised 7-94)**

### **A. OUTFALL SYSTEM CONSTRAINTS**

The Cabezon Channel is a combined irrigation flood control channel with a 2750 acre watershed. The portion of the Cabezon Channel Watershed modeled by the SAD 223 Drainage Management Plan consists of approximately 526 acres which drains to the desilting pond located at the headwaters of the channel. The remaining 2225 acres is located north of Skyview Acres and west of the Corrales Main Canal. The area consists primarily of rural development with minimal drainage controls or improvements. The drainage from this area enters Cabezon Channel via the Corrales Main Canal. The impending development associated with the SAD 223 project combined with the uncertainty surrounding the Corrales Main Canal drainage prompted a study of Cabezon Channel's capacity. Reference the Cabezon Channel Capacity Analysis, Easterling & Associates, Inc. – June 1993. The capacity analysis made some idealistic assumptions about future flood control improvements within the Corrales Main Canal Watershed. Based on these assumptions, the analysis showed that the peak in the Corrales Main Canal will occur after the SAD 223 peak. The net effect is only the base irrigation flow of 50 cfs will add directly to the SAD 223 peak. The report satisfied AMAFCA's concerns as documented in a letter dated December 10, 1993 contained in Appendix A. Unfortunately, it was not practical to correlate the Cabezon capacity analysis with the SAD 223 Drainage Management Plan due to the specialized assumptions and techniques used to analyze the Corrales Main Canal Watershed. Therefore, the peak flow rates and peak timing may differ between the reports, but the overall results are the same.

The 100-year AHYMO "9-91" analysis of the Cabezon Channel Outfall System calculated a peak rate of 490 cfs at the junction of the Cabezon Channel and the Corrales High Ditch. This peak flow rate was based on the following conditions:

1. Fully developed condition within SAD 223 with approximately 50% on-site ponding.
2. The existing condition for the contributing portion of N.M. 528 and the adjacent area to the north.
3. Developed condition for the contributing area of Skyview Acres.
4. A 50 cfs flow rate from the Corrales High Ditch.

## B. SYSTEM DESCRIPTION

### Street/Storm Drain Portion

The proposed SAD No. 223 drainage improvements within the Cabezon watershed will discharge to the Cabezon system at the stilling basin located immediately upstream of the upper transition structure. A 60-inch RCP will convey flows from the intersection of Ellison Drive and NM 528 northward in Ellison to the vacated Corrales Main Canal alignment and then northwest to the stilling basin at the head of Cabezon Channel. The system extends westward in Ellison from NM 528 to Coors Bypass in 48-inch to 36-inch RCP. In this reach, the system was sized to keep one lane (of ultimate six lanes) dry in the 10-year storm, and collect ponded runoff from Tracts M, G-1, and G-2, and Cottonwood Drive north of Seven Bar Loop Road. The entire 100-year storm runoff is collected at NM 528, with ~~no~~ flows being allowed to cross NM 528 or westbound Ellison above ground. The system branches at Coors Bypass. A branch of 36-inch to 24-inch RCP stretches north in the Bypass to collect street flows and ponded flows from Tract B9-J, B-10 (Corrales Pointe Apartments) and B9-D.

Another branch of 30-inch to 24-inch RCP storm drain extends south to Seven Bar Loop Road where flows from Coors Bypass, Seven Bar Loop Road west of the Bypass are intercepted in order to satisfy "one lane dry" criteria. Ponded flows from portions of Tracts N-2A-1 and N-2A-2 are collected as well.

Refer to the Drainage Report for the Trails at Seven Bar South Subdivision May 3, 1993 prepared by Bohannan-Huston, Inc. for Drainage Analysis Associated with Tracts N-2A-1 and N-2A-2.

Flows from future Ellison west of Coors Bypass, ponded flows (future) from Tracts B-9G, B-9H, B-9E, B-9F, and B-9D are intercepted and, along with flows from the south Bypass leg and Cibola High School, are discharged into a 15.3 acre-feet regional detention pond located east of Cibola High School and west of Coors Bypass on Tract N2-B.

The discharge from this pond is connected to the east leg of the Ellison Road storm drain in a 24-inch RCP at a junction with the north leg of the Bypass line.

Discharge from the pond is limited to 11.6 cfs by an orifice plate at the outlet structure. Regional detention pond depth was fixed by clearance requirements at the 24-inch master plan sewer crossing of the pond outfall in the Coors Bypass and Ellison intersection, and the grade of the future storm drain in west Ellison.

### Channel Portion

Tracts O-1A-1 and O-1A-2 of Seven Bar Ranch (59.3 acres) do not drain to the storm drain system in Ellison Road, but rather drain to three 30-inch by 42-inch arch-pipe

CMP's under NM 528 which in turn drain to the stilling basin at the upstream, end of Cabezon Channel through a temporary concrete lined trapezoidal channel. SAD No. 223 proposes to construct a retaining wall along the south side of the existing channel to provide at least 2' of freeboard.

The design hydrology and hydraulics and a schematic of the Cabezon Channel Outfall system are enclosed (Tables 1 through 4 and Sheets 1 through 4).

## **IV. CALABACILLAS ARROYO OUTFALL SYSTEM (Revised 7-94)**

### **A. REPORT REFERENCE**

This portion of the SAD 223 Drainage Management Plan is discussed in the Drainage Report for Cottonwood Mall and SAD 223 Part 2 prepared by Bohannan-Huston, Inc., April 1992 and approved by the City of Albuquerque in June of 1992. A copy of the approval letter is contained in Appendix A.

## **V. INTERIM CONDITIONS (7-94)**

### **A. GENERAL DESCRIPTION**

The storm drainage system proposed for SAD 223 was designed for fully developed contributing areas. With the exception of the Mall Site and streets, the balance of the contributing area is expected to develop in the near future. The SAD 223 improvement plans include temporary facilities to control runoff sediment and peak flow rates from the undeveloped tracts of land during the interim period. Temporary Easements have been (or are being) acquired to allow for construction and operation of the temporary facilities.

### **B. TEMPORARY FACILITIES**

The temporary drainage facilities consist of desilting/detention ponds and minor diversion dikes and channels to convey flows to them.

#### Sediment Control

The temporary ponds have been designed to remove the majority of the sediment from flows generated on the undeveloped areas before they are discharged to the storm drain system. A supplementary report titled "Sediment Analysis for the SAD 223 Cabezon Channel Outfall System" (Reference 6) reports the results of an analysis performed to predict the effect sediment will have on the Cabezon Channel Outfall System in the 100-year storm. The analysis demonstrates that sediment will not be a problem in the storm drain system.

#### Peak Flow Rates

The temporary ponds have been designed to reduce peak flow rates to less than the established allowable flow rates from the individual tracts in the fully developed condition. Hydrologic analysis of the undeveloped areas and respective desilting/detention basins discharging to the Cabezon Channel Outfall System was performed with AMAFCA's AHYMO "9-91." Peak flow rates and volumes for the 100-year storm are summarized on Sheet 6 of this report.

#### Maintenance

The desilting/detention ponds were designed under the assumption that sediment accumulation will be removed annually and after major storms. The sediment storage volume provided in the temporary ponds is equal to the average annual sediment yield plus the sediment yield from the 100 year storm. If sediment removal is performed as previously described, the ponds will always have volume available to function properly in the 100 year storm. The elevation corresponding to the top of the average annual sediment storage volume has been noted on the construction drawings for use by City Maintenance forces.
